Problem 4.1. Composition is defined for *two* morphisms. If more than two morphisms are given, e.g.:

$$A \xrightarrow{f} B \xrightarrow{g} C \xrightarrow{h} D \xrightarrow{i} E$$

then one may compose them in several ways, for example:

$$(ih)(gf), \quad (i(hg))f, \quad i((hg)f), \quad \text{etc.}$$

so that at every step one is only composing two morphisms. Prove that the result of any such nested composition is independent of the placement of the parentheses.

Solution. Let $Z_m \in \text{Obj}(C)$ and $f_m \in \text{Hom}(Z_{m+1}, Z_m)$ for every $m \in \mathbb{N}$. Let n be the number of morphisms we're composing. We will use induction on n .

Base case: Suppose $n = 3$. Then, since C is a category, we have $f_1(f_2f_3) = (f_1f_2)f_3$.

Induction: Suppose that all parenthesizations of f_1, \dots, f_{j-1} under composition are equivalent for all $1 \leq j < n$. Then, for some $1 < k \leq n$, let α be some parenthesization of f_1, \dots, f_{k-1} , and let β be some parenthesization of f_k, \dots, f_n . Any parenthesization of f_1, \dots, f_n will then be of the form $\alpha\beta$. By associativity and our inductive hypothesis, we have $\alpha = ((f_k \dots f_{n-1})f_n)$, and so

$$\begin{aligned} \alpha\beta &= (f_1 \dots f_{k-1}) ((f_k \dots f_{n-1})f_n) \\ &= ((f_1 \dots f_{k-1})(f_k \dots f_{n-1})) f_n \\ &= ((\dots ((f_1f_2)f_3) \dots) f_n \end{aligned}$$

as desired. ■

Problem 4.2. In Example 3.3 we have seen how to construct a category from a set endowed with a relation, provided this latter is reflexive and transitive. For what types of relations is the corresponding category a groupoid?

Solution. Recall that a *groupoid* is a category in which every morphism is an isomorphism. Let \mathbf{C} be a category as defined in Example 3.3, and let (S, \sim) be the category's designated set and relation. \mathbf{C} is a groupoid if \sim is symmetric.

Proof. Let (a, b) be a morphism from a to b in \mathbf{C} . By our definition of \mathbf{C} , we have $a \sim b$. Since \sim is symmetric, we then have $b \sim a$, and so (b, a) is also a morphism in \mathbf{C} (from b to a). Composing these, we have $(a, b)(b, a) = (b, b) = \text{id}_b$. Similarly, we also have $(b, a)(a, b) = (a, a) = \text{id}_a$, making (a, b) an isomorphism as desired. ■

Problem 4.3. Let A, B be objects of a category \mathbf{C} , and $f \in \text{Hom}_{\mathbf{C}}(A, B)$ a morphism.

Solution. .

1. If f has a right-inverse, then f is an epimorphism.

Proof. Let $f \in \text{Hom}_{\mathbf{C}}(A, B)$ be a morphism, $g \in \text{Hom}_{\mathbf{C}}(B, A)$ its right-inverse, and $\alpha_1, \alpha_2 \in \text{Hom}_{\mathbf{C}}(A, Z)$ morphisms for some $Z \in \text{Obj}(\mathbf{C})$ with $\alpha_1 f = \alpha_2 f$. We then have

$$\begin{aligned}\alpha_1 &= \alpha_1(fg) \\ &= (\alpha_1 f)g \\ &= (\alpha_2 f)g \\ &= \alpha_2(fg) \\ &= \alpha_2\end{aligned}$$

making f an epimorphism. ■

2. The converse of 1 does not hold; that is, there exists in some category \mathbf{C} an epimorphism that does not have a right-inverse.

Proof. The category obtained by endowing \mathbb{Z} with the relation \leq contains morphisms that satisfy this property. Let \mathbf{C} be this category; $a, b \in \text{Obj}(\mathbf{C})$ such that $a \neq b$ (so $a < b$); $f \in \text{Hom}(a, b)$; $z \in \text{Obj}(\mathbf{C})$ such that $b \leq z$; and $\alpha_1, \alpha_2 \in \text{Hom}(b, z)$. That $\alpha_1 f = \alpha_2 f$ implies $\alpha_1 = \alpha_2$ is trivially true since $\text{Hom}(b, z)$ has exactly one morphism, so f is an epimorphism.

However, since $a < b$, $b > a$, meaning $\text{Hom}(b, a)$ has no morphisms. Thus, f has no right-inverse. ■

Problem P. Prove that the composition of two morphisms is a monomorphism. Deduce that one can define a subcategory \mathbf{C}_{mono}
